This volume reviews the microtextural literature of the last twenty-five years since the publication of Sand Grain Surface Texures by D.H. Krinsley and J. Doornkamp, in 1973, which inaugurated the use of the SEM in sedimentology. For over four decades, the SEM has proved itself to be the instrument of choice in the analysis of microstructures, whether they be mineral collages or intergrowths ...

Schist is a strongly foliated medium-grade metamorphic rock. It is characterized by an abundance of platy or elongated minerals (micas, chlorite, talc, graphite, amphiboles) in a preferred orientation. Varieties of this rock type share similarities in appearance (schistosity) but may be highly variable in composition.

4.2. Scanning electron microscopic (SEM) observations of quartz surface textures. Application of SEM techniques to study the surface textures of quartz grains is a potential tool in palaeoclimatic studies. This is due to the fact that surface textures are easier to modify and they preserve an imprint of the last depositional environment.

The alluvium consists of sand, clayey sand, clayey silt and minor stringers and beds of quartz and chert gravel. The sediments are generally micaceous, poorly sorted and range in particle size from clay to gravel. Bedding is thin, crude to massive and local ly cross bedded. The alluvium is as much as thirty feet thick in the study area.
