However, the Q test only informs us about the presence versus the absence of heterogeneity, but it does not report on the extent of such heterogeneity.

Recently, the I² index has been proposed to quantify the degree of heterogeneity in a meta-analysis. In this paper, the performances of the Q test and the

If confidence intervals for the results of individual studies (generally depicted graphically using horizontal lines) have poor overlap, this generally indicates the presence of statistical heterogeneity.

We have learned the details for two chi-square tests, the goodness-of-fit test, and the test of independence. Now we focus on the third and last chi-square test that we will learn, the test for homogeneity. This test determines if two or more populations (or subgroups of a population) have the same distribution of a single categorical variable.
